Submitted for open access publication under the terms and conditions of the Creative Commons Attribution (CC BY) license (http://creativecommons.org/licenses/by/4.0/). Abstract: The development of the construction world is driven by the demands of meeting various needs, such as in this case study, namely the construction of the Bantul satpol PP Building to meet the needs of the legal apparatus. However, according to the United Nations Environtment Program in the Global Status Report for Buildings and Construction (2021) states that this development has a significant environmental impact, construction projects are responsible for 36% of energy consumption and 37% global CO2 emissions by 2020. Therefore, this research aims of achieving Greenhouse Gas Emission (GHG) efficiency using the Life Cycle Assessment (LCA) method. Data analysis was applied through the Autodesk Revit program to get the material schedule and LCA approach within the scope of Cradle to Gate using ISO 14040 and 14044 guidelines. The structure of foundations, slabs, columns and beams became the object of research because the constituent materials in the form of concrete and steel are considered as CO2 GHG contributors with the largest percentage, reaching 75% of the total emissions released (Luo et al., 2016). The analysis results show that the largest GHG estimate is located in the structural work of the Cradle to Gate scope which reaches 1,657,880.04 KgCO2eq with the most critical process unit which is the material production process unit. Thus, project construction management can look for the best alternatives related to material selection or methods in the material production process that can reduce GHG emissions. This research can be applied to create a sustainable construction.

**Keywords:** Construction Management, Greenhouse Gas Emissions, Life Cycle Assessment.

### Introduction

Technological developments in the field of construction continue to be encouraged as a form of adjustment to the times that demand a large quantity of construction. Thus, creative solutions are needed to increase the effectiveness of cost, time and quality. One of the advanced technologies that is a creative solution in helping and encouraging the pace of improvement in the field of construction development is Building Information Modeling (BIM) (Zubair, 2024). Building Information Modeling (BIM) has become one of the promising developments in the field of construction and architecture in recent years (Prabhkaran et al., 2020). The use of BIM provides support for building programs, site analysis, orientation of buildings, building mass plans, and construction. The use of BIM is also used to answer the interests and problems in the construction sector which have been known as the triple constraints of time, cost, and quality (Toroxel, 2024). Thus, BIM is known as 5D, namely data, vector drawings, virtual coordination, schedule simulation, and cost estimation.

One analysis related to the environmental impact of a construction implementation is to use the Life Cycle Assessment (LCA) approach. LCA is a method to evaluate inputs, outputs, and potential environmental impacts in the life cycle of a product system. The impact reviewed start from the collection and processing of raw materials, manufacturing, use, maintenance, to the end of the building's operating period (Morsi et al., 2022).

Several studies have been conducted to examine LCA estimation. This research focuses on concrete structures. The consideration behind this research is the design of concrete structures which are considered to have large enough dimensions with the use of cement as a constituent of concrete material which is the largest contributor to GHG emissions. Therefore, it is necessary to consider concrete design by calculating the GHG emissions produced using the LCA approach as a benchmark for decision making. From this research, it is expected that the best alternative can be obtained for the selection of appropriate and efficient and optimal methods and materials so as to obtain greenhouse gas emission efficiency at the implementation stage of the Satpol PP Building Construction project in Bantul Regency.

## Methodology

This research was conducted at the Satpol PP Building Construction Project in Bantul Regional Government Office Complex II, East Ring Road Manding St., Trirenggo, Bantul, D.I Yogyakarta, which has a building area of approximately 982 m<sup>2</sup> and a land area of 2.618 m<sup>2</sup> built with various types of rooms. However, this research is limited to certain structures in the Satpol PP Building Construction Project.

Figure 1. Research Location

The analysis method used in this research is to use the Building Information Modeling (BIM) methods with Autodesk Revit and Life Cycle Assessment (LCA) methods. The analysis in this research uses 5 stages, starting from a literature study to find the main and supporting data of the research such as as-built drawings and LCA database. After that, the data is inputted in Autodesk Revit to get the material schedule. The quantity take off from the material schedule is processed with the LCA method which produces an output of greenhouse gas emissions on the project according to the quantity take off, energy used, and total distance transportation. Finally, the recommendation stage is carried out which is the stage of delivering the results of the analysis and alternatives offered as a basis for consideration of the desired emission effectiveness. The following is a flow chart of the 5 stages above:

Figure 2. Research flow chart

## **Result and Discussion**

## **Re-design**

Author conducted a re-design based on data obtained from the project with the Building Information Modeling method using Autodesk Revit. The data used is in the form of As Built Drawing. The template used in Revit is a structural template. The following are the results of the 3D modeling re-design.

Figure 3. 3D Modeling View of Re-design based on As-built Drawing Data

# Quantity take off

The final result of this modeling is a material schedule to obtain a Quantity Take Off (QTO) of structural work which will then be analyzed using LCA method to obtain an estimate of greenhouse gas emissions. The following figure is a display of one of the QTO's for the 2<sup>nd</sup> floor main beam work with a total concrete volume of 33,47 m<sup>3</sup>

# **Energy uses**

After the quantity material data is complete, the next step that is needed calculating process of energy used, as well as mobilization data. The following table is the data that the author uses:

Electricity Demand of Bantul Regency Satpol PP Building Construction Project						
Power	:	7700	Watt			
Electrical Energy	:	272	kWH			
Electrical Costs	:	IDR500,000.00				
Total cost of electricity used for c	:	IDR3,500,0	00.00			
Total electrical energy used during	:	1904	Kwh			

 Table 3. Calculation of the Amount of Energy Used

Water requirement of Bantul Regency Satpol PP Building Construction					
Project					
Water density in concrete	:	170	kg/m3		
Concrete total volume	:	289.08	m3		
Amount of water used	:	49143.6	kg		
	:	49143.6	litre		

## **Material Mobilization**

The amount of greenhouse gas emissions is also determined based on the distance (S) and repetition of material mobilization. Therefore, the author needs to find data on the source of material (Quarry) used by the project to determine the distance of mobilization as shown in the following table:

Material	Source	Distance from Source	Distance from BP to	Total Distance
		to BP (KM)	Site (km)	(S) (km)
Cement	PT Surya Karya Setiabudi	24.7	19.3	44
Coarse Agregat	SKS Stone Crusher Gamping	2	19.3	21.3
Sand	Ex.Merapi	38	19.3	57.3
Fly Ash	PT Surya Karya Setiabudi	24.7	19.3	44
Admixture	PT Surya Karya Setiabudi	24.7	19.3	44
Water	SKS - PT. Surya Karya Setiabudi	0	0	0
Reinforcement	TB. Rizki Putra Makmur	0	27.8	27.8

Table 4. Calculation of Total Material Mobilization Distance (S)

### Life cycle assessment analysis

The next step after all the required data such as material volume, amount of energy used, and material mobilization distance are available. Greenhouse Gas Emissions (GHG) can be calculated using the following formula:

GHG of Material Production Unit (kgCO<sub>2</sub>e) = V<sub>material</sub> (Kg) x E<sub>factor</sub> (KgCO<sub>2</sub>e/Kg)

GHG of Transportation Unit (kgCO<sub>2</sub>e) = W<sub>material</sub> (Kg) x S (km) x FE<sub>truck</sub> (KgCO<sub>2</sub>e)x 2 x

Repetition

## GHG of Concrete Mixing Unit (kgCO<sub>2</sub>e) = Time (h) x E<sub>factor mixer</sub> (KgCO<sub>2</sub>e/h)

# GHG of Concrete Construction on Site Unit (kgCO<sub>2</sub>e) = Time (h) x Tools E<sub>factor</sub> (KgCO<sub>2</sub>e/h)

Emission Factor (E<sub>factor</sub>) of tools and materials based on LCA database and ecoinvent database.

**Tablel 5.** Emissions Factor of material

No	Material	Emissions Factor (KgCO2e/kg)
1	Cement	1.0670
2	Agregat	0.0032
3	Reinforcement	2.0000
4	Additive	0.6900

Tablel 6. Emissions of truck 7.5 metric ton/1ton.km

Emissions Gas	Emissions Factor (KgCO2eq)
Carbon Dioxide	0.353

Tablel 7. Emissions of truck 16-32 metric ton/1ton.km

<b>Emissions</b> Gas	Emissions Factor (KgCO2eq)
Carbon Dioxide	0.119

The following are the Greenhouse Gas Emissions (GHG) of CO<sub>2</sub>e generated of the structural construction of the Satpol PP Building Development Project, Bantul Regency, D.I Yogyakarta with the scope of Cradle to Gate resulting from the calculation of the LCA method.

Tablel 8. Recapitulation of GHG Emissions of Each Process Unit of Cradle to Gate Scope

No	Unit Process	Stages	Emissions (Kg CO2e)
1	Material Production	Aggregate Production	1,652,899.06
	Process	Cement Production	
		Admixture Production	
		Fly Ash Production	
		Reinforcement Production	
2	Mobilization to the	Aggregate Mobilization	3,898.45
	Batching Plan	Cement Mobilization	
		Admixture Mobilization	
		Fly Ash Mobilization

4	Site Mobilization		Mobilization of Concrete from	
			Batching Plan	_
			Mobilization of Reinforcement	
			Steel	
5	Construction	Process	Installation of Reinforcing Steel	1,082.52
	on Site		Concrete Casting	
Total				1,657,880.04

## Alternative solutions to reduce emissions

From the calculations in the table above, it can be concluded that the material production process is the biggest greenhouse gas emitter. Therefore, to reduce emissions, it can be done by substituting materials using the least emitting materials to reduce or even replace materials or materials that have the greatest potential to produce emissions. For example, granite waste can be used as a substitute for cement. In addition, it can also be done by making careful calculations related to volume requirements so that there is no excessive production of materials so that emissions from the production process unit will be reduced.

## Conclusion

Based on the research and data analysis that has been carried out, conclusions can be drawn that answer the existing problem formulation, as follows, based on the structural modeling using Autodesk Revit 3D BIM Method, the foundation, column, beam, and slab work resulted in concrete volumes of 12.19 m<sup>3</sup>, 44.56 m<sup>3</sup>, 136.99 m<sup>3</sup>, and 95.34 m<sup>3</sup> respectively and rebar volumes of 266,472.33 cm<sup>3</sup>, 1,025,252.7 cm<sup>3</sup>, 2,222,284.39 cm<sup>3</sup>, and 837,096.76 cm<sup>3</sup> respectively. The process unit of the construction project of the Satpol PP Building that produces CO<sub>2</sub> emissions with the scope of Cradle to Gate consists of 5 process units, namely Material Production, Mobilization (Transportation) to the Batching Plan, Concrete Mixing, mobilization (Transportation) to the Site, and the construction process.

The total amount of greenhouse emissions (Kg CO<sub>2</sub>eq) analysis if the Cradle to Gate scope of the Satpol PP Building Construction Project is 1,657,880.04 Kg CO<sub>2</sub>eq. Based on the results of data analysis and processing, it can be concluded that the most critical process unit for CO<sub>2</sub>e emissions is the material production process unit with emission reaching 1,652,899.04 Kg CO<sub>2</sub>eq.
